

Proofs

Miaoyan Wang, May 20, 2020

Proof. Note that $f \in \mathcal{F}$ implies that, there exist $\mathbf{B}^{\text{true}} \in \mathbb{R}^{d_1 \times d_2}$, such that $\text{rank}(\mathbf{B}^{\text{true}}) \leq r$ and f has the following representation,

$$\mathbb{P}(Y = 1|\mathbf{X}) = f(\mathbf{X}) = \langle \mathbf{X}, \mathbf{B}^{\text{true}} \rangle, \quad \text{for all } \mathbf{X} \in \mathbb{R}^{d_1 \times d_2}.$$

The low-rank SMM minimizes the sample version of the following population function

$$L_\pi(\mathbf{B}) \stackrel{\text{def}}{=} \mathbb{E}[\ell_\pi(\mathbf{B})] = \mathbb{E} \left\{ \sum_{y_i=1} [1 - \langle \mathbf{X}_i, \mathbf{B} \rangle]_+ + \sum_{y_i=-1} [1 + \langle \mathbf{X}_i, \mathbf{B} \rangle]_+ \right\},$$

where the expectation is over $(\mathbf{X}_i, y_i) \sim_{\text{i.i.d}} \mathcal{X} \times \mathcal{Y}$. Straightforward calculation shows that

$$\frac{1}{n} L_\pi(\mathbf{B}) = \mathbb{E} \left\{ [1 - Y \langle \mathbf{X}, \mathbf{B} \rangle]_+ \mathbb{1}(Y = 1) + [1 + Y \langle \mathbf{X}, \mathbf{B} \rangle]_+ \mathbb{1}(Y = -1) \right\},$$

where $(\mathbf{X}, y) \sim \mathcal{X} \times \mathcal{Y}$. Let $\hat{\mathbf{B}} = \arg \min_{\{\mathbf{B}: \text{rank}(\mathbf{B}) \leq r\}} L(\mathbf{B})$. We will prove that $\hat{\mathbf{B}} = \mathbf{B}^{\text{true}}$. Note that

$$\begin{aligned} \frac{1}{n} L_\pi(\hat{\mathbf{B}}) &= \mathbb{E} \left\{ [1 - Y \langle \mathbf{X}, \hat{\mathbf{B}} \rangle]_+ \mathbb{1}(Y = 1) + [1 + Y \langle \mathbf{X}, \hat{\mathbf{B}} \rangle]_+ \mathbb{1}(Y = -1) \right\} \\ &= \mathbb{E} \left\{ (1 - Y \langle \mathbf{X}, \hat{\mathbf{B}} \rangle) \mathbb{1}(Y = 1) \right\} \\ &= \mathbb{E}(Y = 1) - \mathbb{E} \left\{ Y \mathbb{1}(Y = 1) \langle \mathbf{X}, \hat{\mathbf{B}} \rangle \right\}. \end{aligned}$$

We note that

$$\begin{aligned} \mathbb{E} \left\{ Y \mathbb{1}(Y = 1) \langle \mathbf{X}, \hat{\mathbf{B}} \rangle \right\} &= \mathbb{E}_{\mathbf{X}} \left\{ \langle \mathbf{X}, \hat{\mathbf{B}} \rangle \mathbb{E}_{(\mathbf{X}, Y)} [Y \mathbb{1}(Y = 1) | \mathbf{X}] \right\} \\ &= \mathbb{E}_{\mathbf{X}} \left\{ \langle \mathbf{X}, \hat{\mathbf{B}} \rangle \left(\mathbb{P}(Y = 1 | \mathbf{X}) - \frac{1}{2} \right) \right\} \\ &= \mathbb{E}_{\mathbf{X}} \left\{ \langle \mathbf{X}, \hat{\mathbf{B}} \rangle \left(\langle \mathbf{X}, \mathbf{B}^{\text{true}} \rangle - \frac{1}{2} \right) \right\}. \end{aligned}$$

Therefore, the optimal $\hat{\mathbf{B}}$ must satisfy $\text{sign} \langle \mathbf{X}, \hat{\mathbf{B}} \rangle = \text{sign} (\langle \mathbf{X}, \mathbf{B}^{\text{true}} \rangle - \frac{1}{2})$. □
